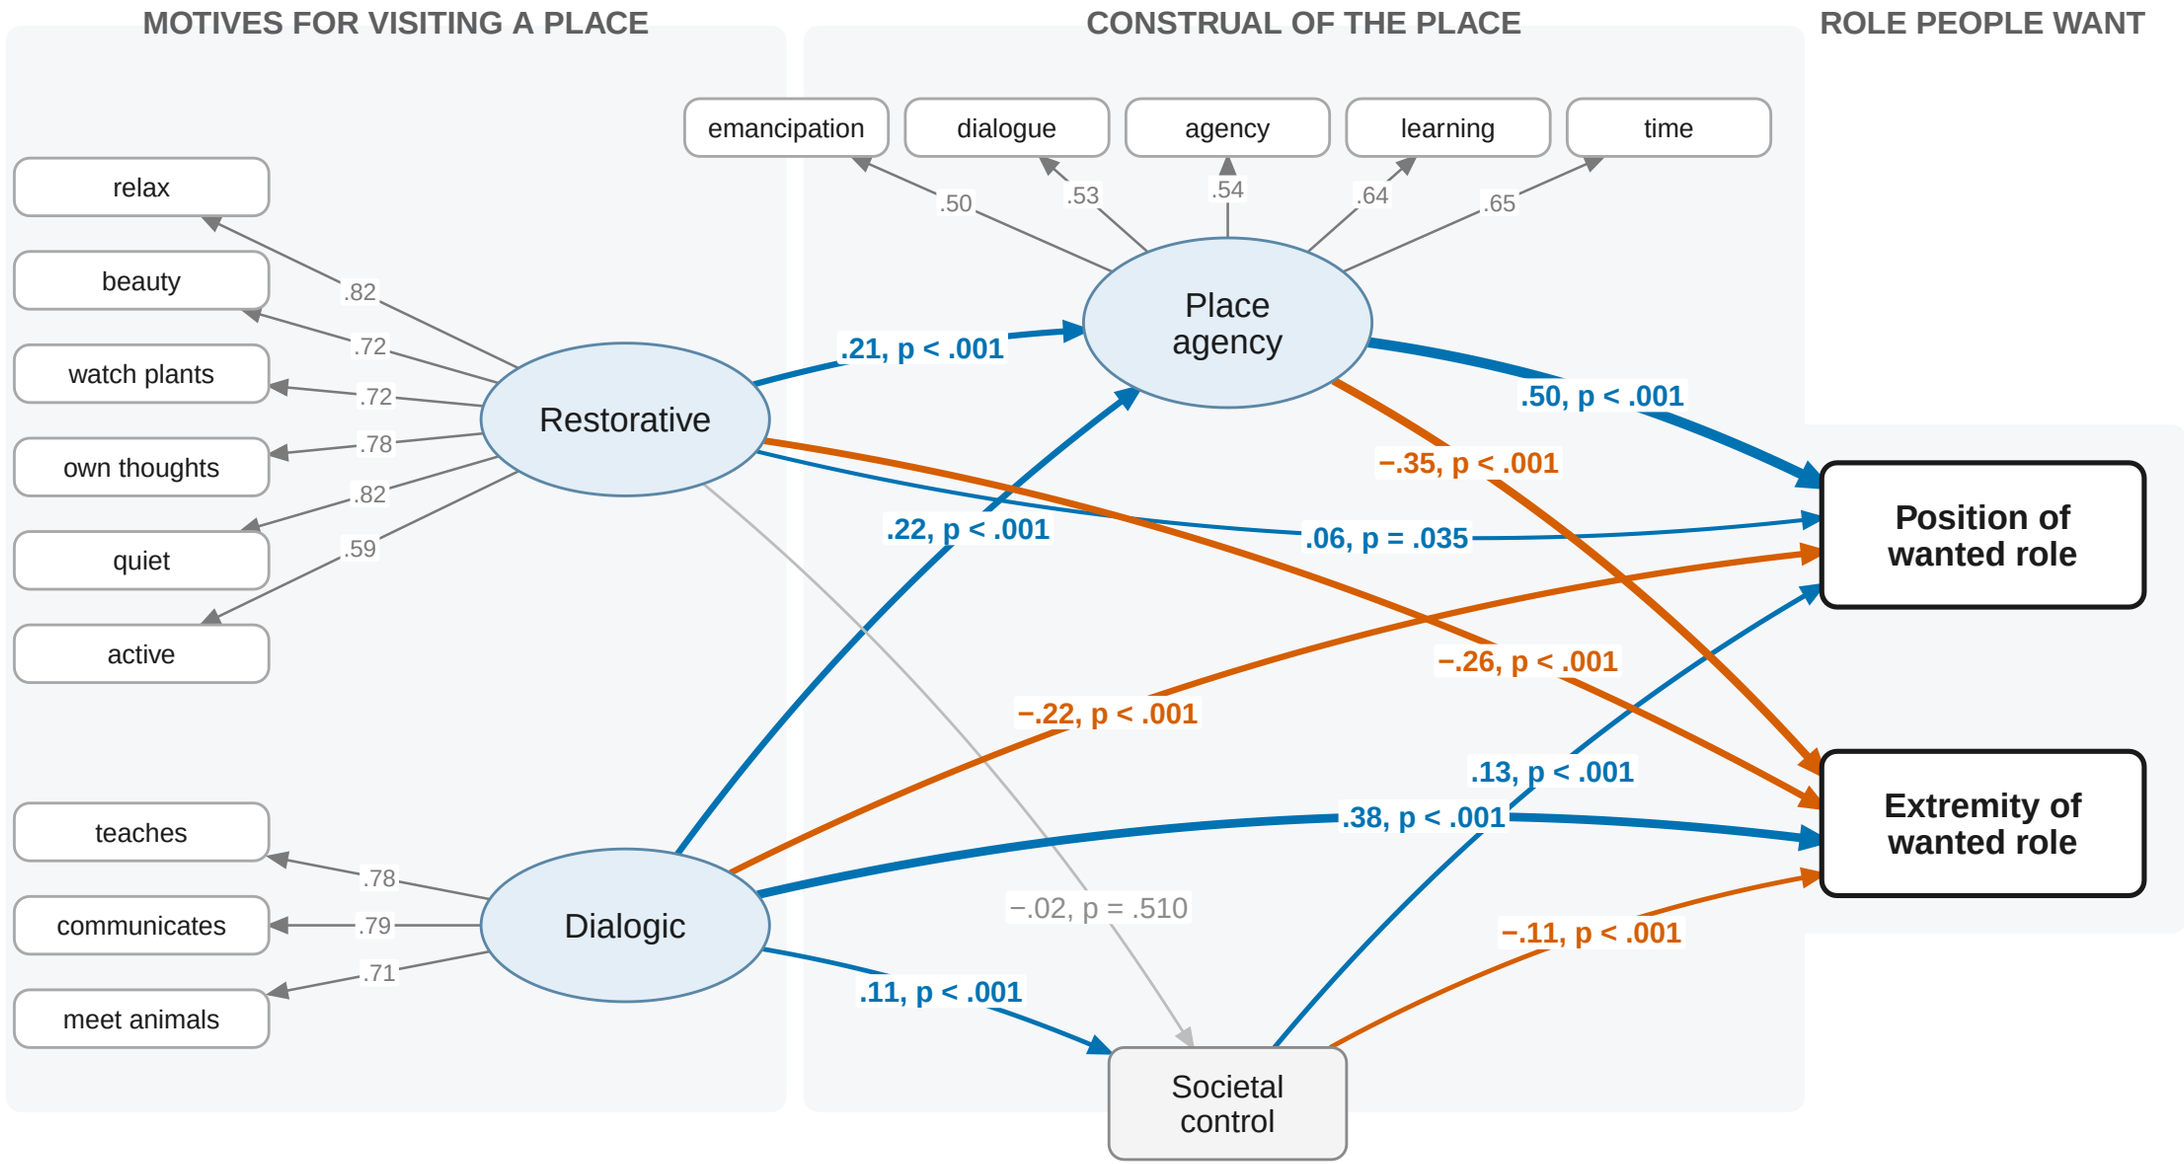
How experience of a place reaches the role people want: through the agency they grant it

Standardised estimates, both motives entered together. Line width grows with the size of the path.



WLSMV, n = 2,489, ordinal indicators. Position runs from Master (1) to Object (6): positive = a role further from Master. Extremity = choosing either pole.
Age, gender, education and country are in the model and not drawn: age and gender go with place agency (+.18, −.20)
but have no significant path to the wanted role, and education has only a borderline path to extremity (higher −.06, primary +.05).
Societal control is its mean score. Source: 28_story_model.R
